

# Impact of a mixed ocean layer and the diurnal cycle on convective aggregation

Adrian Tompkins ([Tompkins@ictp.it](mailto:Tompkins@ictp.it)) and Addisu Semie (University of Addis Ababa, Ethiopia)

Follow my Avatar!!!

I'm relaxed! (adaptively)

We devised a cool new method to allow spatial sea surface temperature (SST) variability and a mean SST diurnal cycle in a slab ocean, while eliminating all SST drift. Correct, no drift!!! The trick is to use an adaptive target SST in a relaxation scheme.

Summary of the 6-member ensemble experiments (100 days)

	Ocean thickness	Relaxation Timescale	SST	Diurnal Cycle
MLD20-CONST	20m	1 minute	SST spatial variability almost prohibited by thick ocean layer SST mean constant=28°C	28°C atmospheric heating
MLD1-CONST	1m	1 minute	SST spatial variability large, spatial ocean feedbacks permitted SST mean constant=28°C	28°C atmospheric heating surface spatial response (<0.1°C)
MLD1-DIURN	1m	1.2 hours	SST spatial variability large, spatial ocean feedbacks permitted SST mean also undergoes 0(2.5°C) diurnal cycle Multiday mean=28°C	Daytime max 28°C Nighttime min atmospheric heating surface spatial response (<0.1°C) surface mean response 3°C diurnal

Domain 512<sup>2</sup> km, Δx=2km don't tell anyone

thick mixed ocean layer

thin mixed ocean layer

No SST drift! catch my drift?

This red blob is a bone dry patch, it is a sign of convection self-aggregation starting...

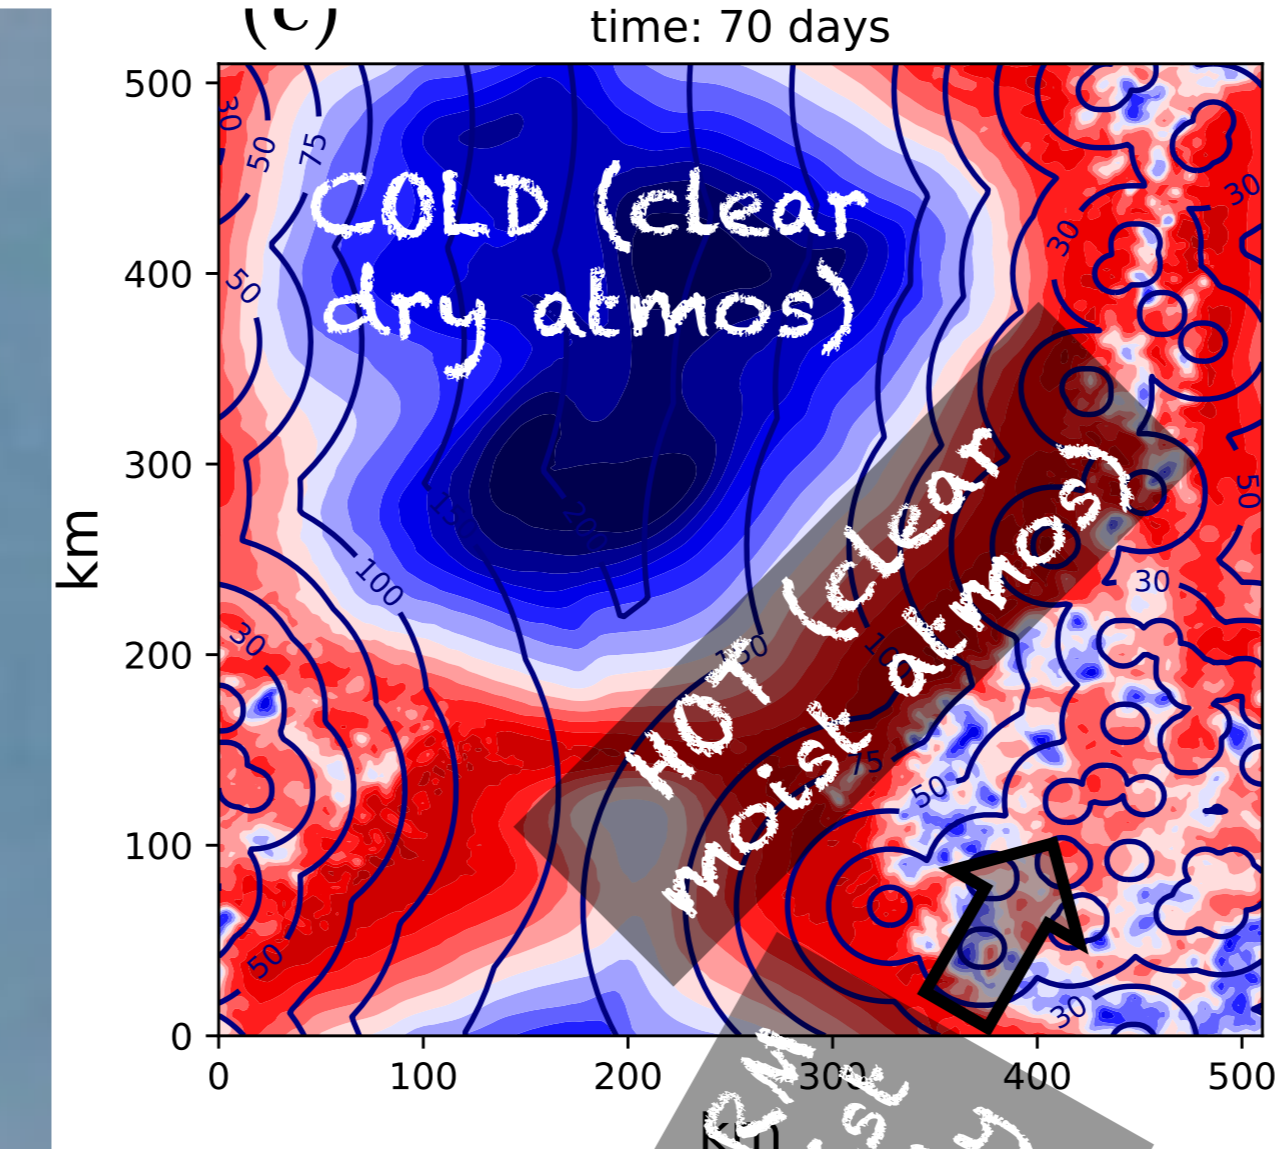

... wait long enough and convection ends up in a single cluster...

it has... (cue echo) AGGREGATED...

woo hoo, So what?

Well it could be important for climate, aggregated states are much drier!

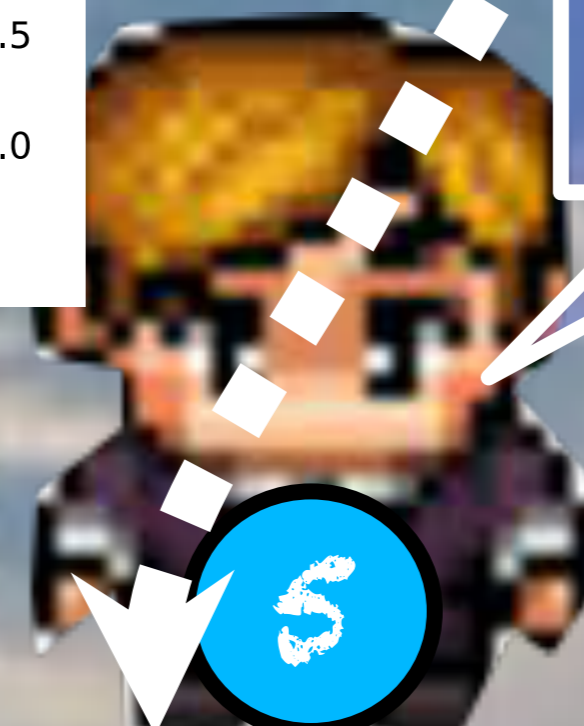

Well first let's look at SST - after aggregation it is divided into 3 clear zones. Note how the convection likes to bunch up to the edges of the hot zones.

I'm not (SW-cloud) forcing you to stay

This feels more eternal than diurnal

The SST variance is initially driven by shortwave (SW)-cloud forcing, and damped by latent heat (LH) fluxes. The thin ocean increases fluxes far from convection and reduces them nearby, delaying aggregation onset...

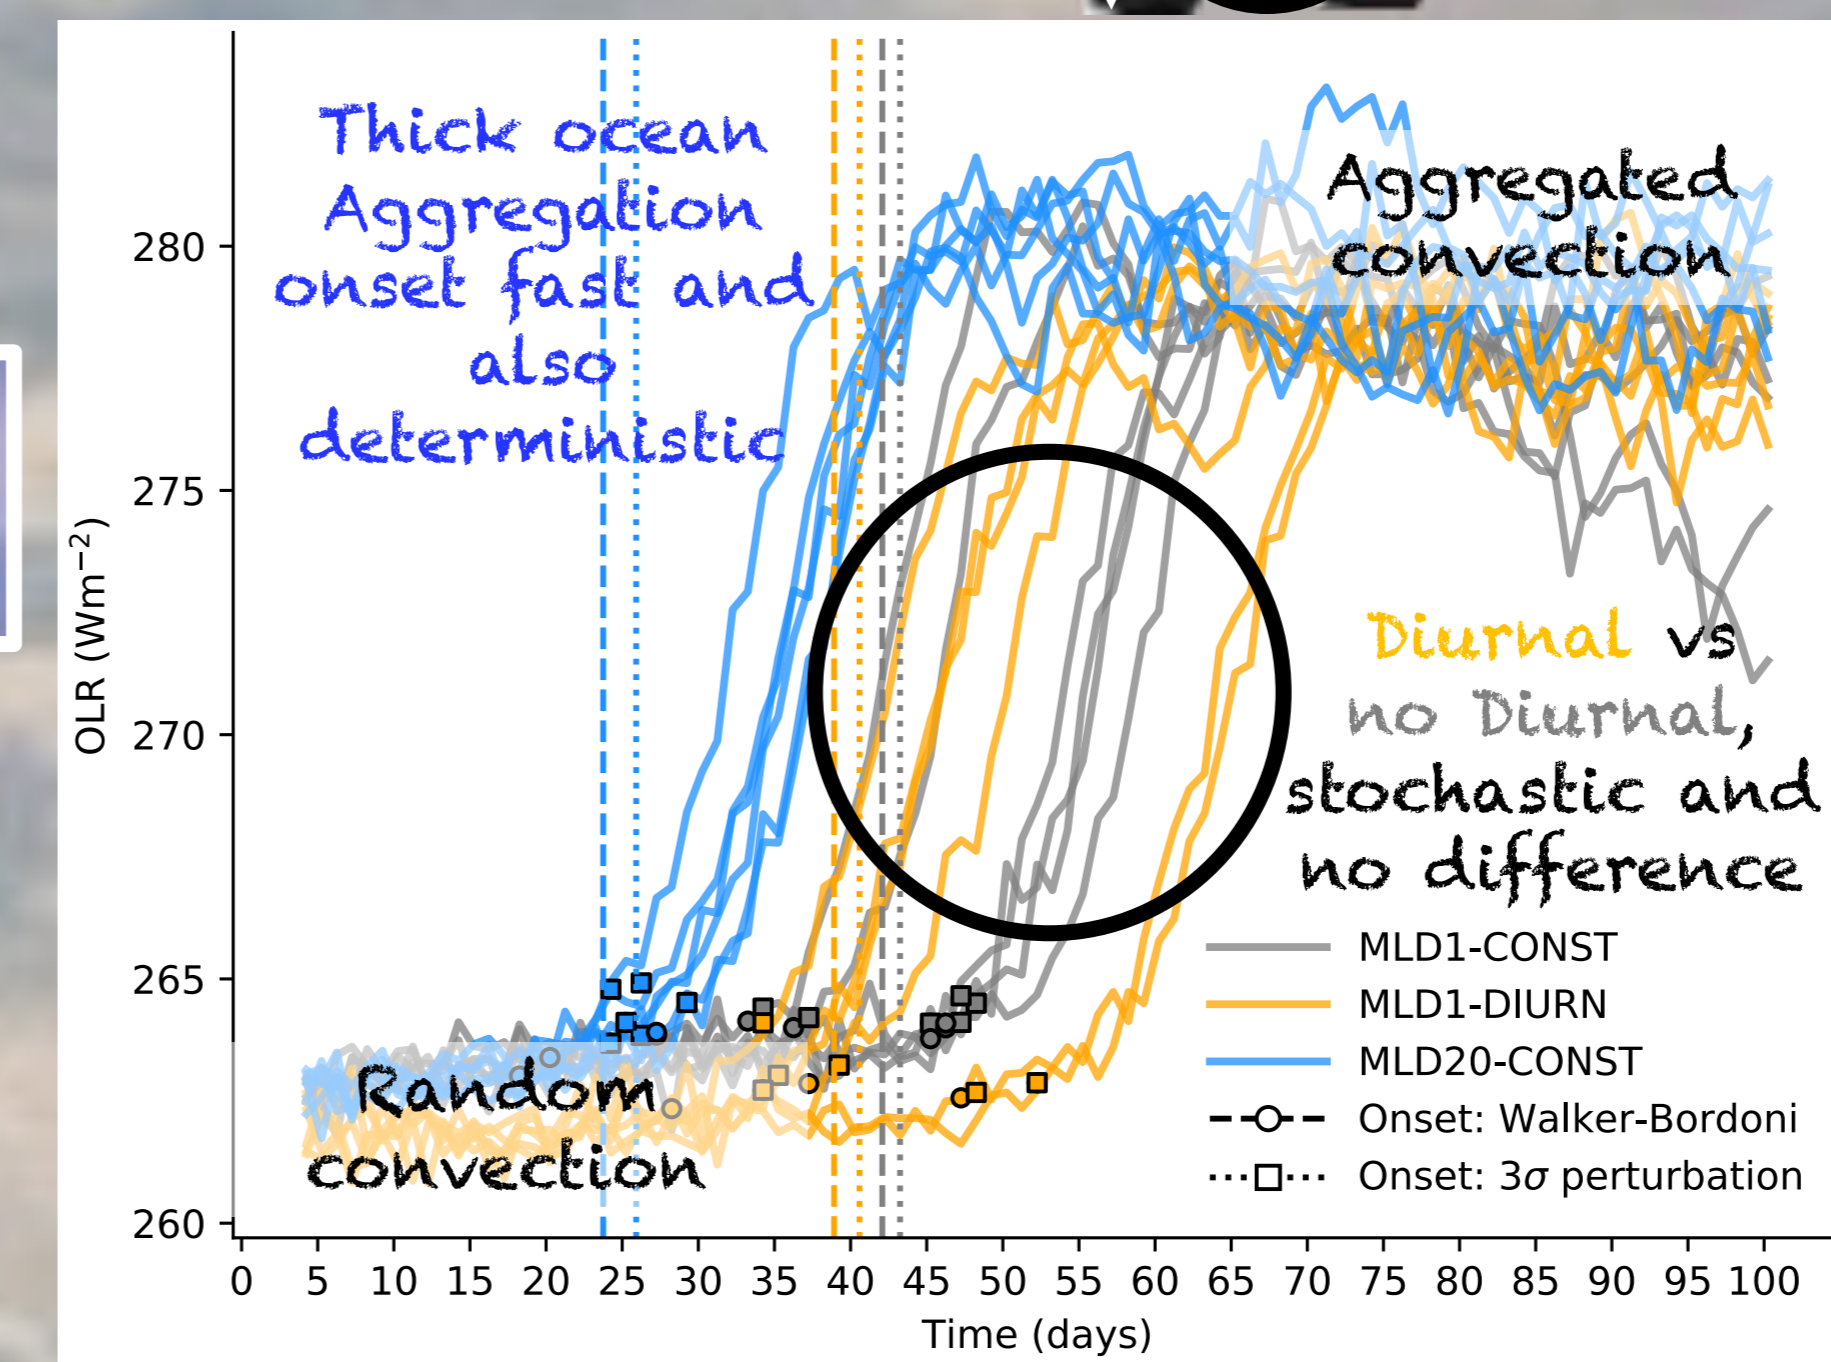

In the paper, we use artificial intelligence (best kind!) to show this is predominately via thermodynamic effects (stability and Δq) not wind.

We almost forgot! What about adding the mean diurnal cycle?

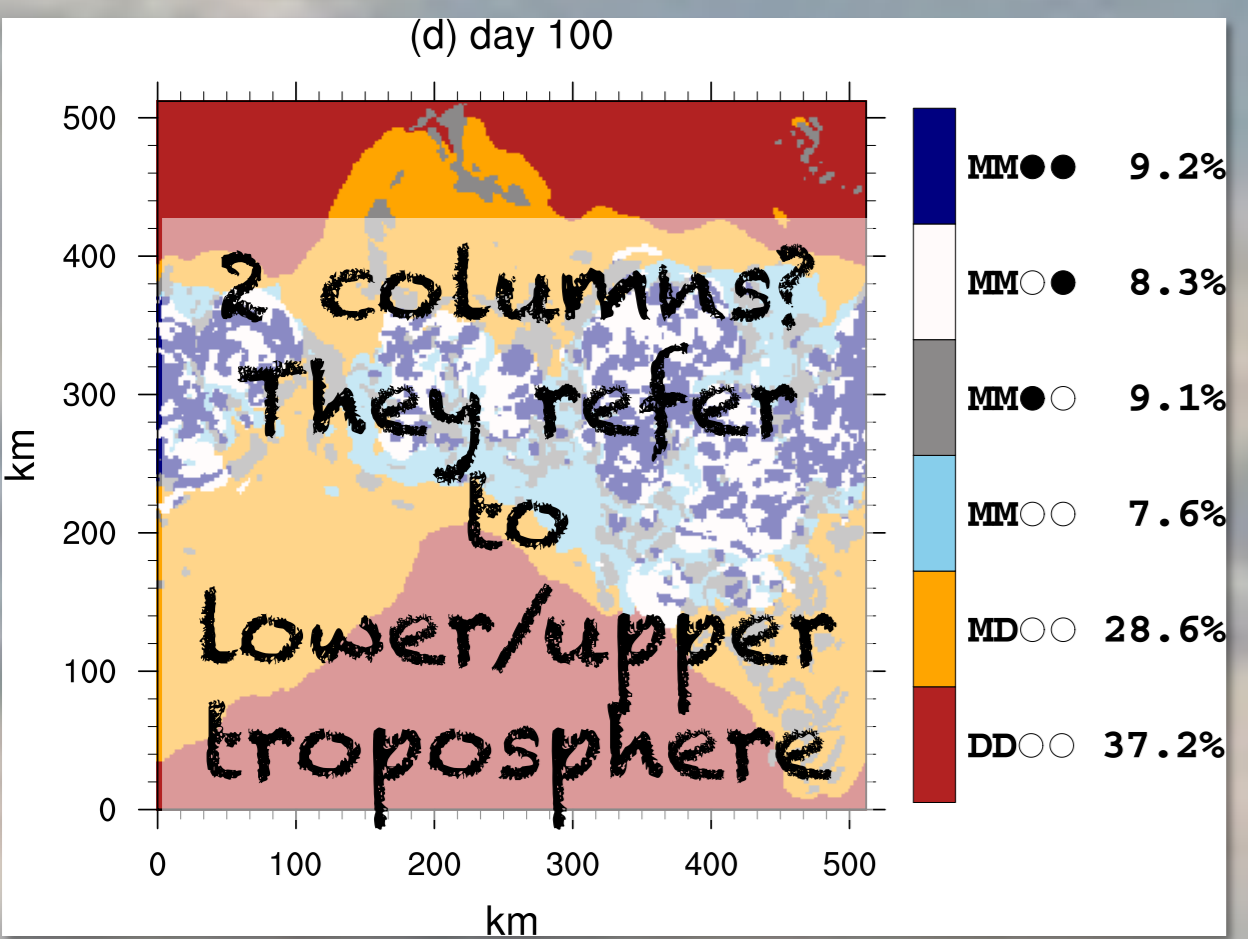

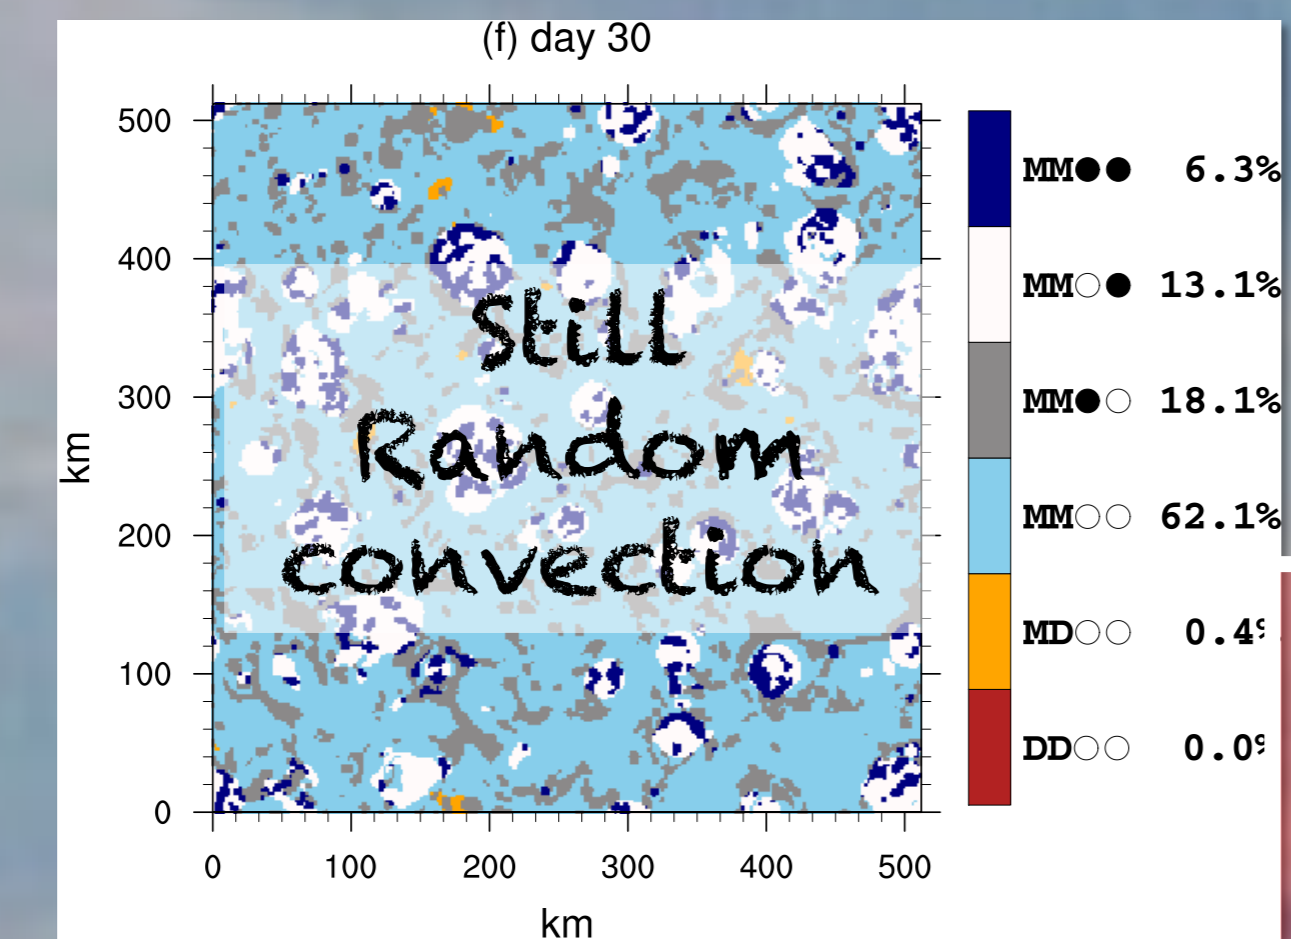

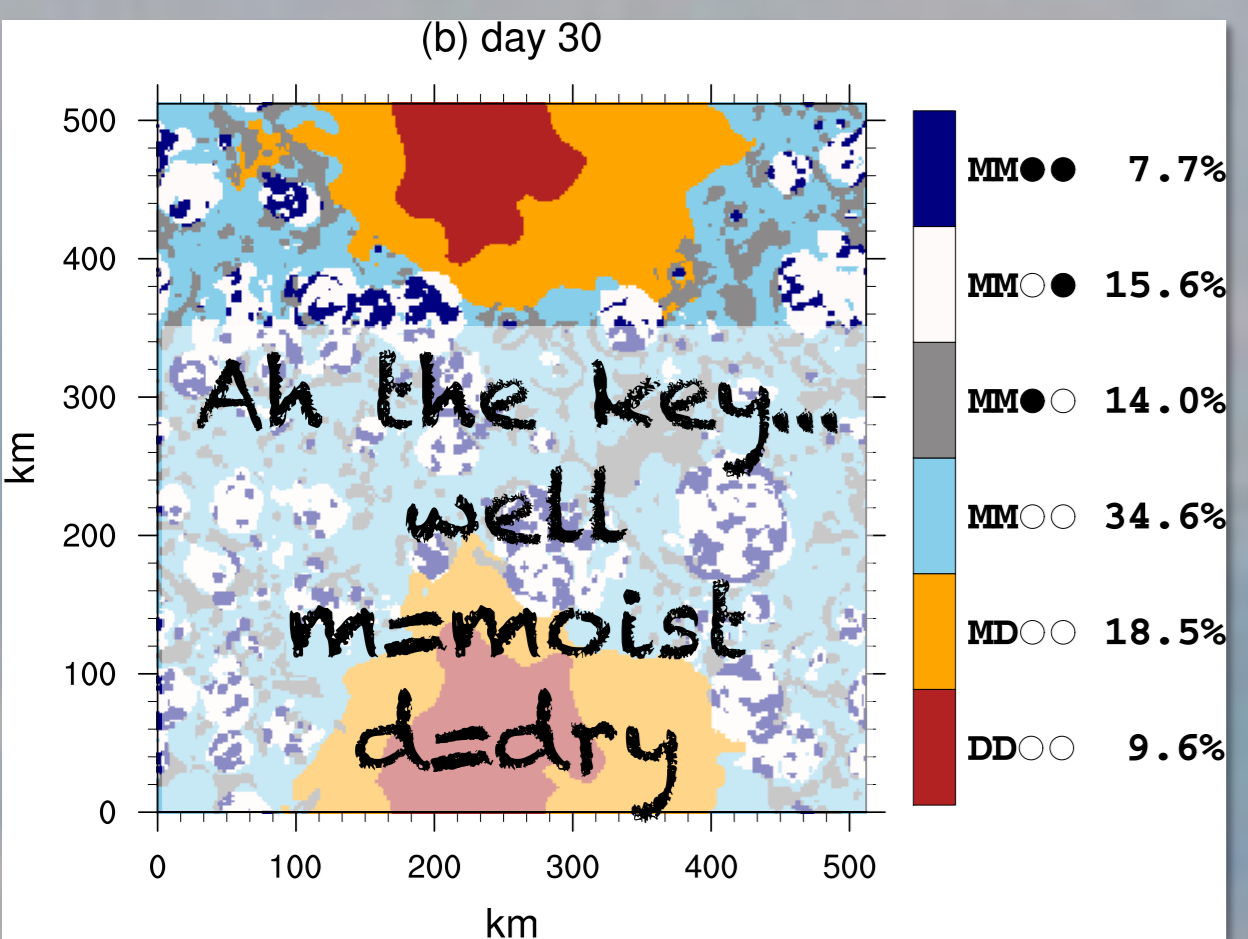

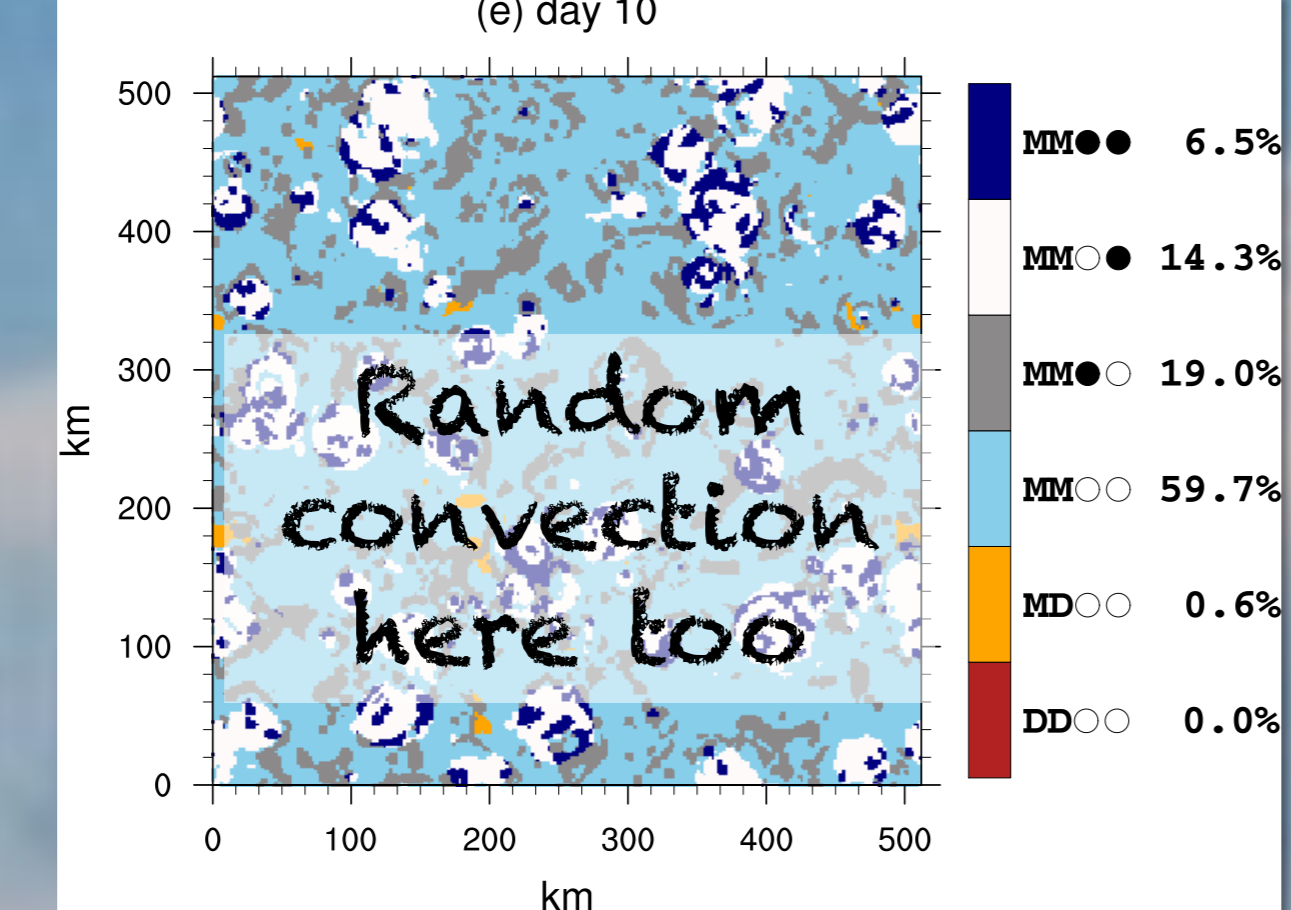

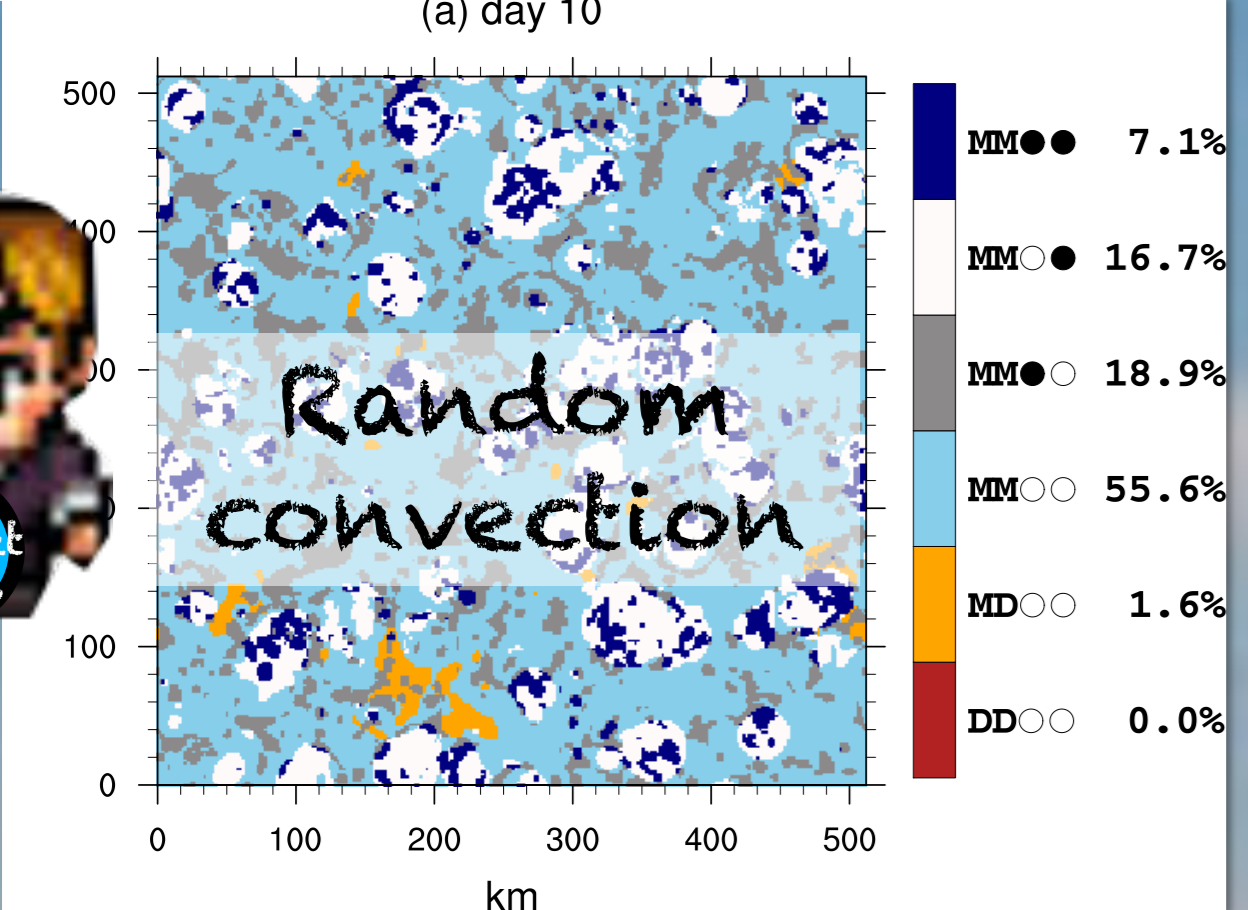

Well it's a bit boring really as it didn't have any additional impact on aggregation speed (look left!)

There are two subtle mechanisms at play involving SST variance and cloud spacing/cold pools, but they are minor and partially cancel, oh well.

Note the highly variable stochastic onset when it is slow, no space here to discuss that... but...

I'm already zoning out

When fixed SSTs or a thick mixed ocean layer is used, the organization starts after 20-25 days

Pop a thin (1m) mixed ocean layer underneath and things take a lot longer to get going. See also the OLR plot lower right. But why? Follow #3

Let's aggregate!!! (COVID compliantly)

What! Still here? ...you want to know more? Yes? Really? Then check out our 2021 paper in JAMES, <https://doi.org/10.1029/2020MS002186>
